
Short Course: Device Research Conference, June 23, 2019, University of Michigan

Beyond 5G: 100-340GHz Transistor, IC, and System Design

*Mark Rodwell,
University of California, Santa Barbara*

Center for Converged Communications & Sensing at THz.

Duration:
5-years; 1/2018-12/2022.

Funding:
about \$36 million total.

Team:
21 Professors,
~65 Ph.D. students

Sponsors:
SRC, DARPA

Focus:
wireless systems,
10-15 years out,
100-340GHz

Wireless above 100GHz

— Services —

— Systems —

— ICs —

— Devices —

Wireless networks: exploding demand.

Immediate industry response: 5G.

28, 38, 57-71(WiGig), 71-86GHz

increased spectrum, extensive beamforming

Next generation (6G ??): above 100GHz..

greatly increased spectrum, massive spectral multiplexing

DOD applications: Imaging/sensing/radar, comms.

140-340GHz Wireless

10Gb mobile communications:

Unlimited information, anywhere.
Capacity well beyond 5G.

TV-resolution wireless imaging:

See, fly, drive perfectly in any conditions.

Benefits of Short Wavelengths

Communications: Massive spatial multiplexing, massive # of parallel channels

Imaging: very fine angular resolution

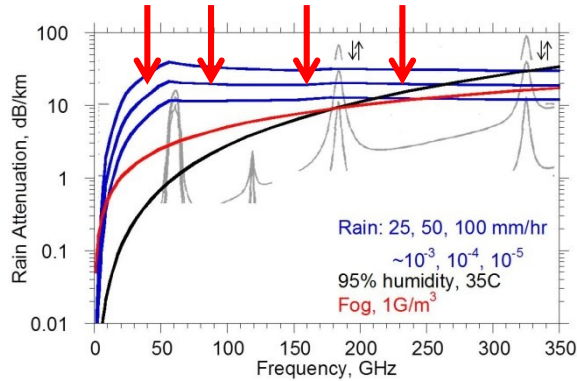

But:

High losses in foul or humid weather.
 High λ^2/R^2 path losses.
 ICs: poorer PAs & LNAs.
 Beams easily blocked.

100-340GHz wireless:
 terabit capacity,
 short range,
 highly intermittent

mm-waves: benefits & challenges

Large available spectrum

(note high attenuation in foul or humid weather)

Massive # parallel channels

Torklinson : 2006 Allerton Conference
Sheldon : 2010 IEEE APS-URSI
Torklinson : 2011 IEEE Trans Wireless Comm.

Need phased arrays (overcome high attenuation)

Need mesh networks

140-340 GHz: Applications

140 GHz spatially multiplexed base station

1 Tb/s spatially-multiplexed base station

256 users/face, 4 faces

1024 total users @ 1 user/beam, 1 Gb/s/beam;

225 m range

Link budget is feasible, but...

Required component dynamic range ?

Required complexity of back-end beamformer ?

Handset:

8 × 8 array

(9×9mm)

140 GHz spatially multiplexed base station

Each face supports 256 beams @ 1Gb/s/beam.

225 meters range in 50 mm/hr rain

Realistic packaging loss, operating & design margins (20dB total)

PAs: 16 dBm P_{out} (per element)

LNAs: 3 dB noise figure

| | | |
|---------------------------------------|------|----|
| Required SNR (measured as E_b/N_0) | 9.8 | dB |
| packaging loss (receiver) | 2 | dB |
| packaging loss (transmitter) | 2 | dB |
| end-of-life hardware degradation | 2 | dB |
| hardware design margin | 2 | dB |
| beam aiming loss (edge of beam) | 2 | dB |
| systems operating margin | 5 | dB |
| path obstruction loss (shadowing) | 5.00 | dB |

75 GHz spatially multiplexed base station

If we use instead a 75GHz carrier,
but constrain the handset to a similar size (8mm×8mm)
and the hub to the same number of elements
then the range becomes 210 meters (vs. 225 meters)

Would be similar performance;
except that PAs, LNAs are poorer @ 140GHz

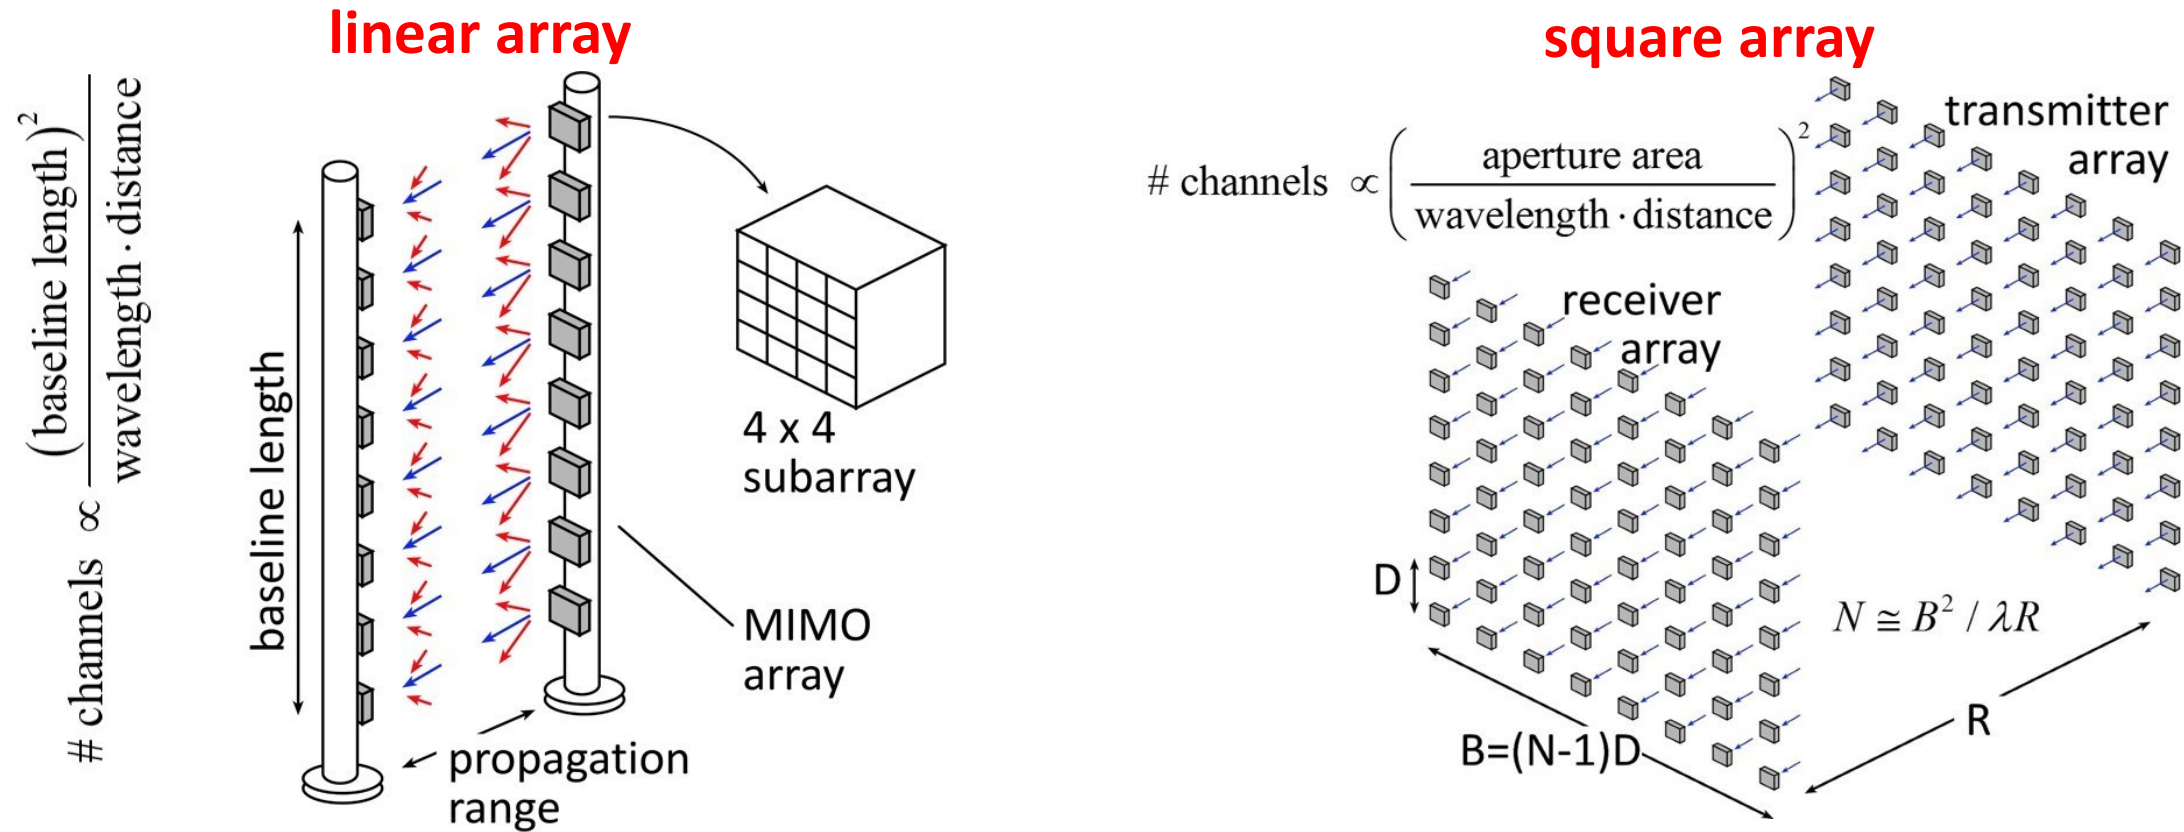

$$\frac{P_{received}}{P_{trans}} = \frac{D_{hub} D_{hand}}{16\pi^2} \left(\frac{\lambda}{R}\right)^2 e^{-\alpha R} \quad D_{hand} = 4\pi A_{hand} / \lambda^2 \quad D_{hub} = D_{element} N_{hub}$$

$$\frac{P_{received}}{P_{trans}} = \frac{D_{hub,element} N_{hub} A_{hand}}{4\pi} \left(\frac{1}{R}\right)^2 e^{-\alpha R} \propto R^0 \cdot e^{-\alpha R}$$

*The hub array is now 9mm×655mm (vs. 5mm×350mm)

340 GHz (or even 650 GHz) backhaul

Sub-mm-wave line-of-sight MIMO network backbone

wireless @ optical speed; link network where fiber is too expensive to place.

340 GHz: 640Gb/s @ 500 meters range; 1.6 meter linear array **(5Tb/s for 8×8 square array)**.

650 GHz: 1.28Tb/s @ 500 meter range; 1.6 meter linear array.

Capacity doubles again if we use both polarizations.

340 GHz 640 Gb/s MIMO backhaul

| | | |
|--|----------|-----|
| Required SNR (measured as Eb/No) | 9.8 | dB |
| packaging loss (receiver) | 2 | dB |
| packaging loss (transmitter) | 2 | dB |
| end-of-life hardware degradation | 3 | dB |
| hardware design margin | 3 | dB |
| beam aiming loss (edge of beam) | 0 | dB |
| systems operating margin | 10 | dB |
| Prec, received power at 1E-3 BER | -33.00 | dBm |
| geometric path loss | 2.07E-06 | |
| geometric path loss, dB | -56.84 | dB |
| path obstruction loss (foliage, glass) | 0.00 | dB |

1.6m MIMO array: 8-elements, each 80 Gb/s QPSK; 640Gb/s total
4 × 4 sub-arrays → 8 degree beamsteering

500 meters range in 50 mm/hr rain; 29 dB/km

Realistic packaging loss, operating & design margins

PAs: 82mW P_{out} (per element)

LNAs: 4 dB noise figure

340 GHz 5 Tb/s MIMO backhaul

500m range in 50mm/hr. rain.

8-element 640Gb/s linear array:
requires 80mW power/element
requires 1.6m linear array

8-element 5Tb/s square array:
same link assumptions
requires 10mW power/element
...10W total radiated power
requires 1.6m square array

140 GHz, 640 Gb/s MIMO backhaul

Why not use a lower-frequency carrier, e.g. 140 GHz ?

8-element 640Gb/s linear array:

same link assumptions

requires 2mW (vs. 80mW) power/element

requires 2.6m (vs. 1.6m) linear array

8-element 5Tb/s square array:

same link assumptions

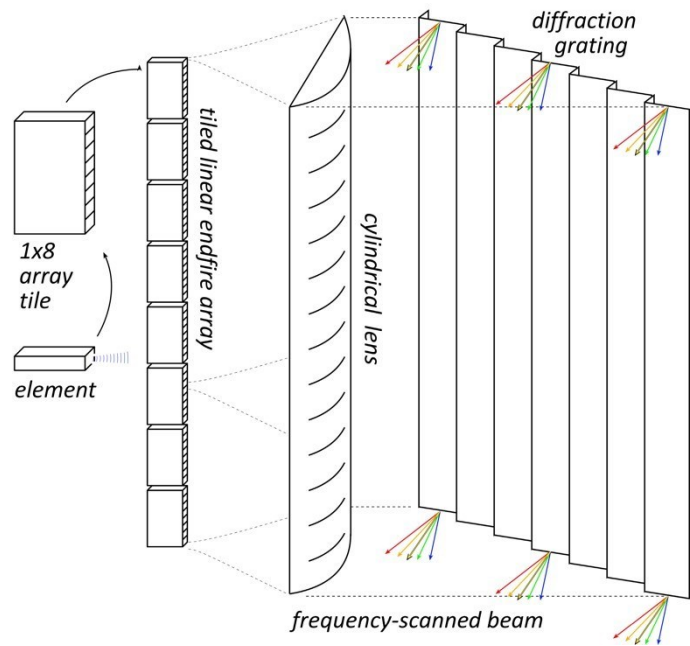

requires 0.25mW (vs. 10mW) power/element

requires 2.6m (vs. 1.6m) square array

64-element square array

High-resolution imaging radar

Proposed demo: 220GHz frequency-scanned system

64×512 pixels, 60Hz refresh

35cm × 35cm aperture

64-element linear array

Target:

0.3m diameter, 10% reflectivity, 300m range

detect with 5dB SNR in 35dB/km fog.

System:

$F=6\text{dB}$, $P_{\text{element}} = 10\text{dBm}$ (10% duty cycle)

DOD-relevant: 140GHz close-range system

256×256 pixels, 10ms image acquisition time

27 cm linear arrays, 256 elements

Target (large bullet):

2cm diameter, 10% reflectivity, 100m

detect with 10dB SNR in 20dB/km rain.

System

$F=6\text{dB}$, → Need 0.4W PAs (10% duty cycle)

(reasonable margins)

Systems

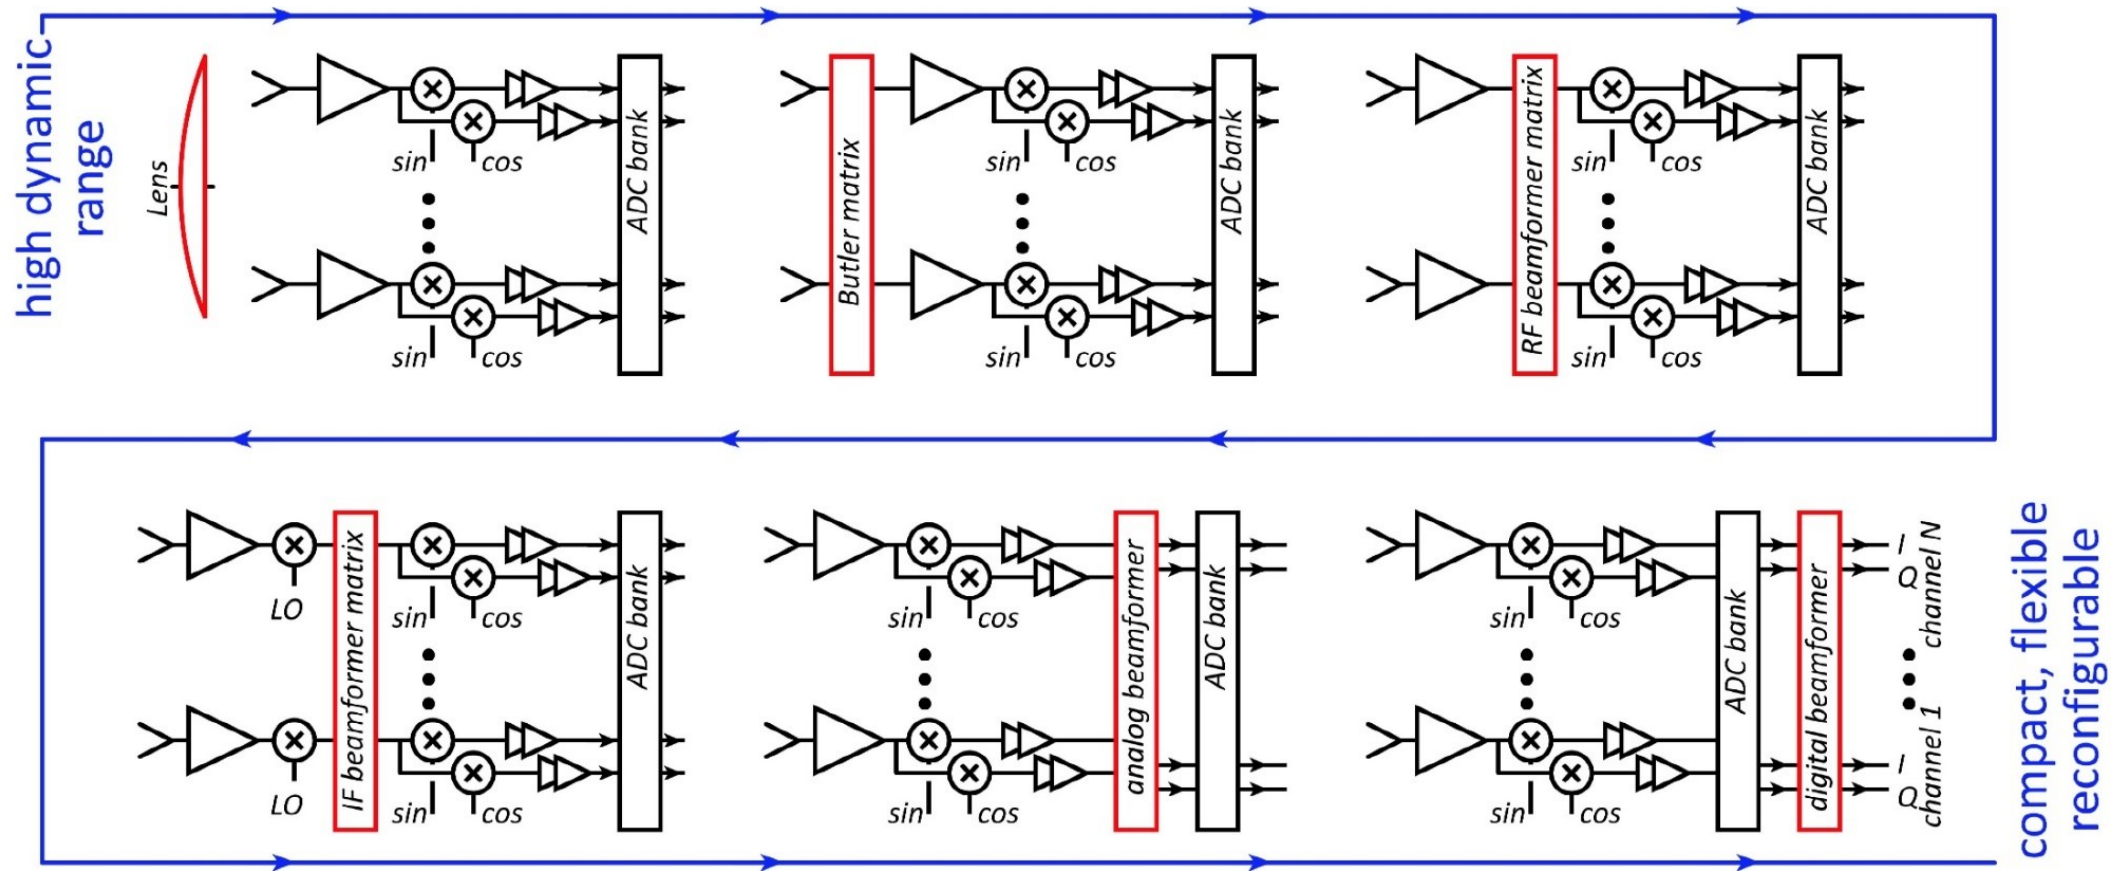

(a) Narrowband scenario.

(b) Wideband scenario.

Beamforming for massive spatial multiplexing

Pure digital beamforming:

dynamic range & phase noise requirements: appear to be manageable ✓✓✓

Digital back-end processing requirements (die area, DC power): being investigated ???

Pure RF beamforming: (focal plane, Butler matrixes, RF beamforming)

Established approach in DOD systems (high dynamic range). Issues of array tiling.

Beamforming for massive spatial multiplexing

Digital beamforming

- ✓ **ADCs/DACs:** only 3-4 bit ADC/DACs required (Madhow, Studer, Rodwell)
- ✓ **Linearity:** Amplifier $P_{1\text{dB}}$ need be only 3dB above average power (Madhow).
- ✓ **Phase noise:** Requirements same as for SISO (Alon, Madhow, Niknejad, Rodwell)

Efficient digital beamforming: beamspace algorithm=complexity $\sim N \times \log(N)$ (Madhow)

Efficient digital beamforming: low-resolution matrix (Studer)

Efficient channel estimation : fast beamspace algorithm (Studer)

Efficiently addressing true-time-delay problem: "rainbow" FFT algorithm (Madhow)

- ✓ **Array-to-backplane interconnect power:** low-power analog baseband 50Ω links (Rodwell)

In progress...

Propagation models and measurements: (Molisch)

Blockage probability, mesh networks, network protocols: (Rangan, Cabric)

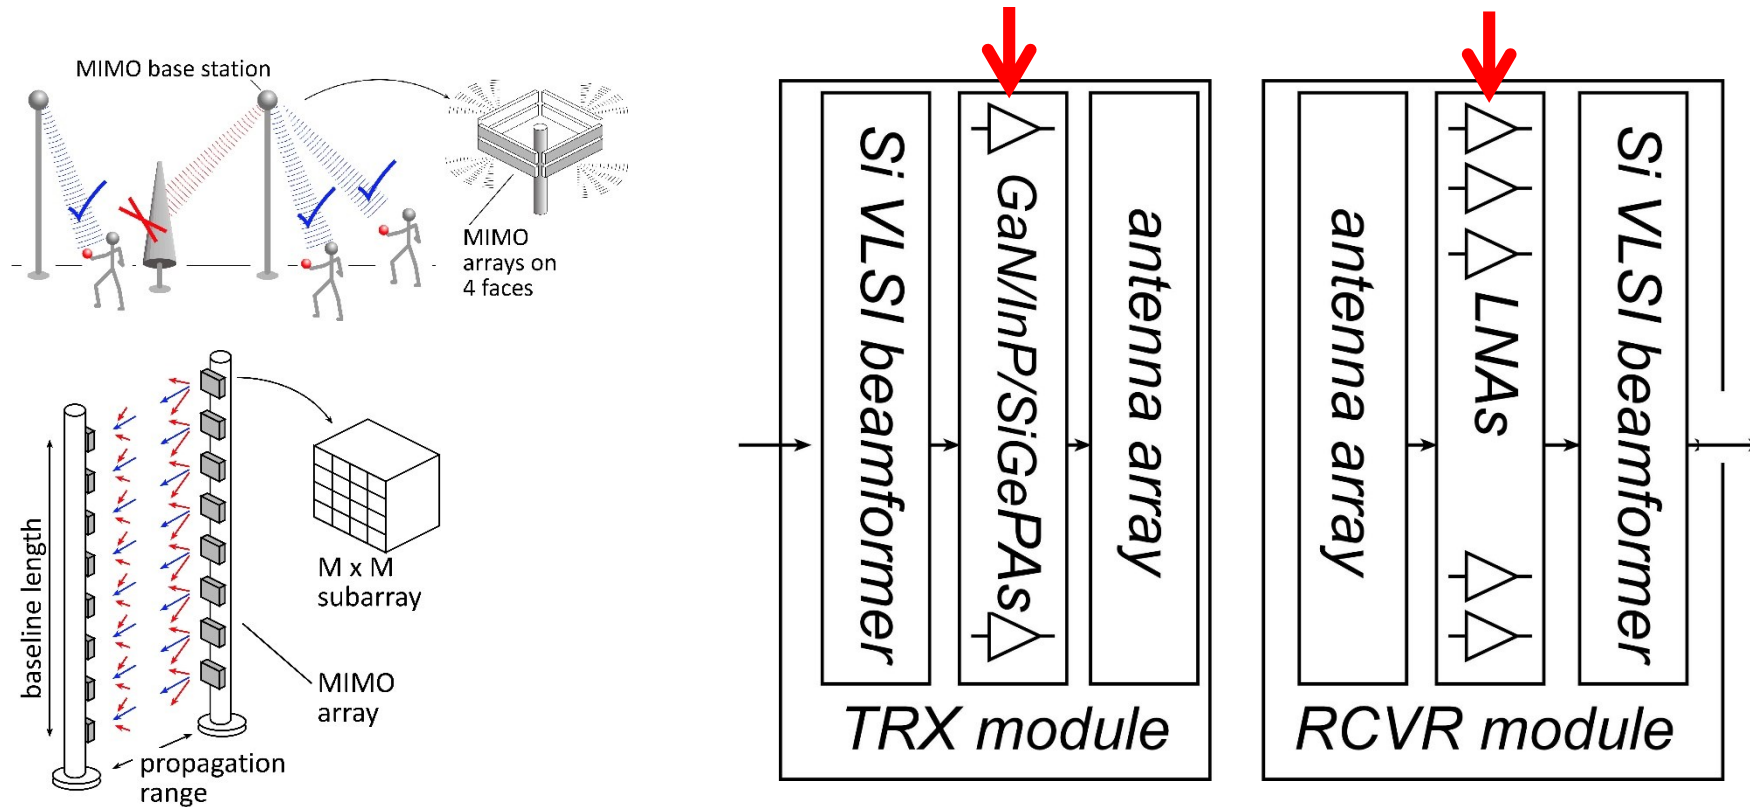

MIMO system power analysis: (Rangan, Cabric, Buckwalter)

Transistors

mm-Wave Wireless Transceiver Architecture

custom PAs, LNAs → power, efficiency, noise
Si CMOS beamformer → integration scale

...similar to today's cell phones.

IC Technologies for 100 + GHz systems

Silicon

baseband processing at all frequencies
RF sections @ 140, 200GHz
PAs, LNAs in short-range 140, 220 GHz links

GaN

high-power amplifiers in long-range 140,220GHz links
(possibly 340GHz ?)

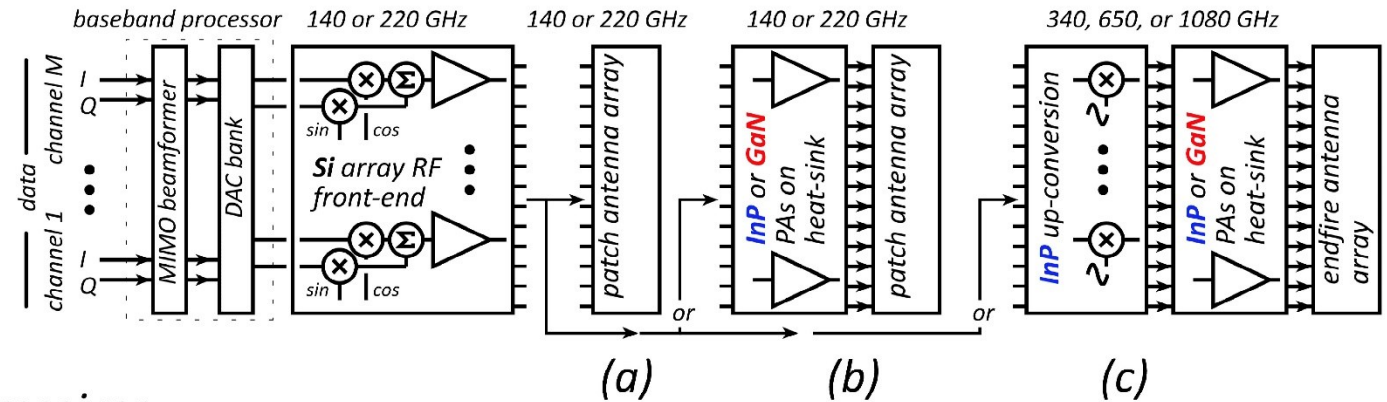

InP HEMT

low-noise amplifiers in long-range 140,220GHz links
low-noise amplifiers @ 340, 650GHz

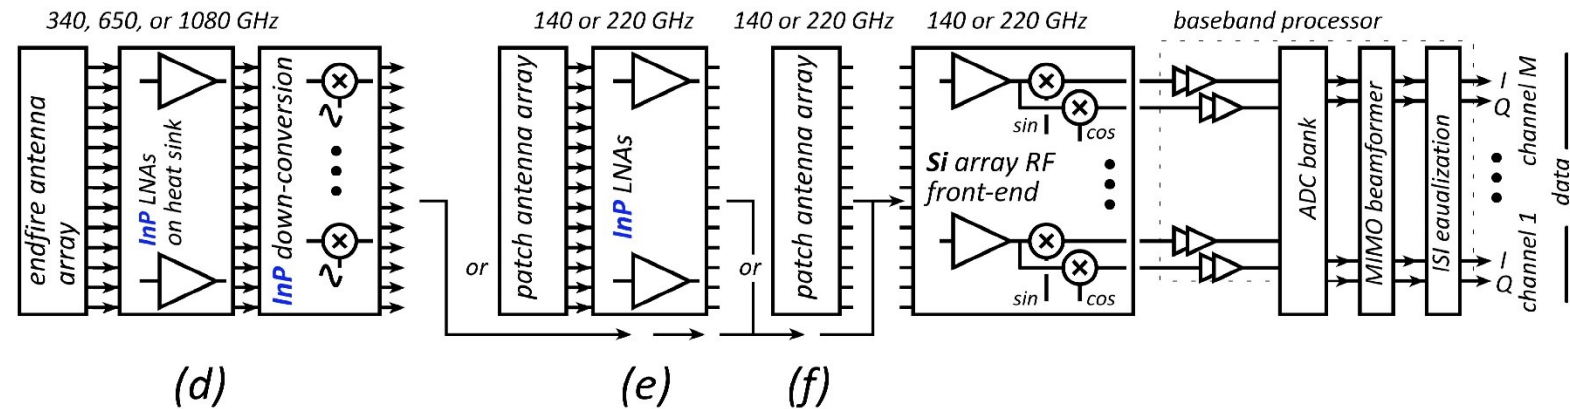

InP HBT

medium-power amplifiers in long-range 140,220GHz links
power amplifiers @340, 650GHz
RF sections @ 340, 650GHz

transmitter

receiver

spatially multiplexed base station

MIMO hub:

140GHz: F= 4dB, P_{avg} =17.5dBm, $P_{sat} \approx 21.5$ dBm
220GHz: F= 4dB, P_{avg} =21dBm, $P_{sat} \approx 25$ dBm

Point-point MIMO:

340GHz: F= 4dB, P_{avg} =9.9dBm, $P_{sat} \approx 13.9$ dBm
650GHz: F= 4dB, P_{avg} =14.5dBm, $P_{sat} \approx 18.5$ dBm?

mm-wave CMOS (UCSB examples)

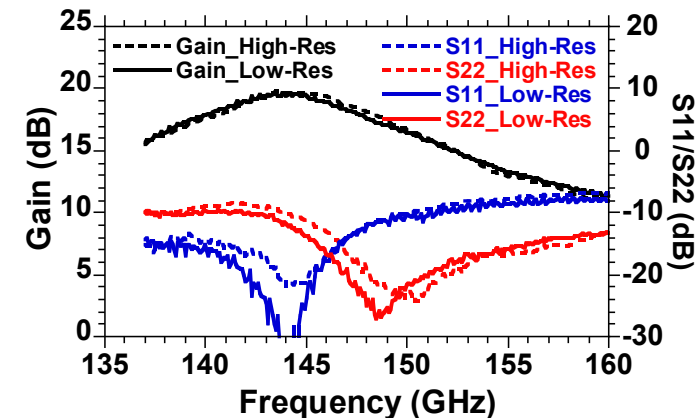

150 GHz amplifier:

IBM 65 nm bulk CMOS, 2.7dB gain per stage Seo et al., JSSC, Dec. 2009

145 GHz amplifier

GF 45 nm SOI CMOS, 6.3 dB gain per stage Kim, Simsek, 2017 BCICTS

mm-Wave CMOS won't scale much further

Gate dielectric can't be thinned

→ on-current, g_m can't increase

Shorter gates give no less capacitance

dominated by ends; $\sim 1\text{fF}/\mu\text{m}$ total

Maximum g_m , minimum $C \rightarrow$ upper limit on f_T
about 350-400 GHz.

Tungsten via resistances reduce the gain

Inac et al, CSICS 2011

Present finFETs have yet larger end capacitances

III-V high-power transmitters, low-noise receivers

Cell phones & WiFi: GaAs PAs, LNAs

mm-wave links need:
high transmit power, low receiver noise

0.47 W @86GHz

H Park, UCSB, IMS 2014

325 GHz, 16mW power amplifier

UCSB/Teledyne: A. Ahmed, 2018 EuMIC Symp.

Integrated ~600GHz transmitter

Teledyne: M. Urteaga *et al*: 2017 IEEE Proceedings

but, only ~1 mW output power

Transistor scaling laws: (V, I, R, C, τ) vs. geometry

Depletion Layers

$$C = \epsilon \cdot \frac{A}{T}$$

$$\tau = \frac{T}{2v}$$

$$\frac{I_{\max}}{A} = \frac{4\epsilon v_{\text{sat}} (V_{\text{appl}} + \phi)}{T^2}$$

Bulk and Contact Resistances

$$R \cong \rho_{\text{contact}} / A$$

contact te rms dominate

Fringing Capacitances

- 1) FET fringing capacitances
- 2) IC interconnect capacitances

Thermal Resistance

Available quantum states to carry current

→ capacitance,
transconductance
contact resistance

Frequency Limits and Scaling Laws of (most) Electron Devices

$$\tau \propto \text{thickness}$$

$$C \propto \text{area} / \text{thickness}$$

$$R_{top} \propto \rho_{contact} / \text{area}$$

$$R_{bottom} \propto \frac{\rho_{contact}}{\text{area}} + \frac{\rho_{sheet}}{4} \cdot \frac{\text{width}}{\text{length}}$$

$$I_{\text{max, space-charge-limit}} \propto \text{area} / (\text{thickness})^2$$

$$\Delta T \propto \frac{\text{power}}{\text{length}} \times \log\left(\frac{\text{length}}{\text{width}}\right)$$

To double bandwidth:

Reduce thicknesses 2:1

Improve contacts 4:1

Reduce width 4:1,

Keep constant length

Increase current density 4:1

Bipolar Transistor Design

$$\tau_b \approx T_b^2 / 2D_n$$

$$\tau_c = T_c / 2v_{sat}$$

$$C_{cb} = \epsilon A_c / T_c$$

$$I_{c,max} \propto v_{sat} A_e (V_{ce,operating} + V_{ce,punch-through}) / T_c^2$$

$$\Delta T \propto \frac{P}{L_E} \left[1 + \ln \left(\frac{L_e}{W_e} \right) \right]$$

$$R_{ex} = \rho_{contact} / A_e$$

$$R_{bb} = \rho_{sheet} \left(\frac{W_e}{12L_e} + \frac{W_{bc}}{6L_e} \right) + \frac{\rho_{contact}}{A_{contacts}}$$

(emitter length L_E)

Bipolar Transistor Design: Scaling

$$\tau_b \approx T_b^2 / 2D_n$$

$$\tau_c = T_c / 2v_{sat}$$

$$C_{cb} = \epsilon A_c / T_c$$

$$I_{c,max} \propto v_{sat} A_e (V_{ce,operating} + V_{ce,punch-through}) / T_c^2$$

$$\Delta T \propto \frac{P}{L_E} \left[1 + \ln \left(\frac{L_e}{W_e} \right) \right]$$

$$R_{ex} = \rho_{contact} / A_e$$

$$R_{bb} = \rho_{sheet} \left(\frac{W_e}{12L_e} + \frac{W_{bc}}{6L_e} \right) + \frac{\rho_{contact}}{A_{contacts}}$$

(emitter length L_E)

Making faster bipolar transistors

| to double the bandwidth: | change |
|---|----------------|
| emitter & collector junction widths | decrease 4:1 |
| current density ($\text{mA}/\mu\text{m}^2$) | increase 4:1 |
| current density ($\text{mA}/\mu\text{m}$) | constant |
| collector depletion thickness | decrease 2:1 |
| base thickness | decrease 1.4:1 |
| emitter & base contact resistivities | decrease 4:1 |

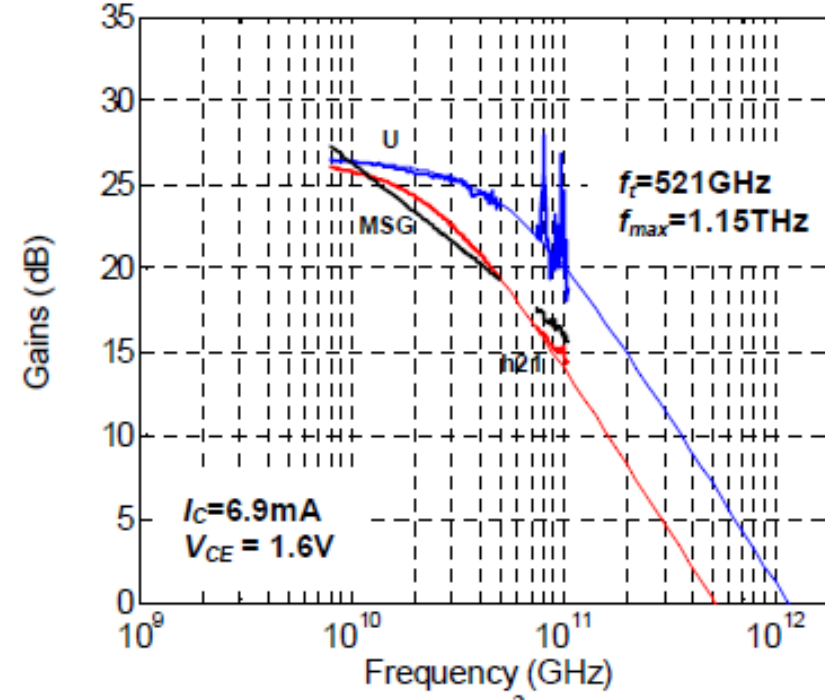

Narrow junctions.

Thin layers

High current density

Ultra low resistivity contacts

Teledyne: M. Urteaga *et al*: 2011 DRC

InP HBTs: 1.07 THz @200nm, ?? @ 130nm

THz HBTs: The key challenges

Obtaining good base contacts

in HBT vs. in contact test structure
(emitter contacts are fine)

Baraskar *et al*, Journal of Applied Physics, 2013

RC parasitics along finger length

metal resistance, excess junction areas

Towards a 2 THz SiGe Bipolar Transistor

Similar scaling

InP: 3:1 higher collector velocity

SiGe: good contacts, buried oxides

Key distinction: Breakdown

InP has:

thicker collector at same f_{τ} ,

wider collector bandgap

Key requirements:

low resistivity Ohmic contacts

note the high current densities

Assumes collector junction 3:1 wider than emitter.

Assumes SiGe contacts no wider than junctions

| | InP | SiGe | |
|---------------------|------|------------|-------------------------------|
| emitter | | | |
| junction width | 64 | 18 | nm |
| access resistivity | 2 | 0.6 | $\Omega\text{-}\mu\text{m}^2$ |
| base | | | |
| contact width | 64 | 18 | nm |
| contact resistivity | 2.5 | 0.7 | $\Omega\text{-}\mu\text{m}^2$ |
| collector | | | |
| thickness | 53 | 15 | nm |
| current density | 36 | 125 | $\text{mA}/\mu\text{m}^2$ |
| breakdown | 2.75 | 1.3? | V |
| f_{τ} | 1000 | 1000 | GHz |
| f_{max} | 2000 | 2000 | GHz |

FETs (HEMTs): key for low noise

2:1 to 4:1 increase in f_τ :
improved noise
less required transmit power
smaller PAs, less DC power
or higher-frequency systems

InP HEMTs: state of the art

First Demonstration of Amplification at 1 THz Using 25-nm InP High Electron Mobility Transistor Process

Xiaobing Mei, et al, IEEE EDL, April 2015 (**Northrop-Grumman**)

FET Scaling Laws (these now broken)

- vertical S/D spacer
- low-K dielectric spacer
- high-K gate dielectric

| FET parameter | change |
|-----------------------------------|--------------|
| gate length | decrease 2:1 |
| current density (mA/mm) | increase 2:1 |
| specific transconductance (mS/mm) | increase 2:1 |
| transport mass | constant |
| 2DEG electron density | increase 2:1 |
| gate-channel capacitance density | increase 2:1 |
| dielectric equivalent thickness | decrease 2:1 |
| channel thickness | decrease 2:1 |
| channel state density | increase 2:1 |
| contact resistivities | decrease 4:1 |

FET Scaling Laws (these now broken)

- vertical S/D spacer
- low-K dielectric spacer
- high-K gate dielectric

| FET parameter | change |
|-----------------------------------|--------------|
| gate length | decrease 2:1 |
| current density (mA/mm) | increase 2:1 |
| specific transconductance (mS/mm) | increase 2:1 |
| transport mass | constant |
| 2DEG electron density | increase 2:1 |
| gate-channel capacitance density | increase 2:1 |
| dielectric equivalent thickness | decrease 2:1 |
| channel thickness | decrease 2:1 |
| channel state density | increase 2:1 |
| contact resistivities | decrease 4:1 |

Gate dielectric can't be much further scaled.

Not in CMOS VLSI, not in mm-wave HEMTs

g_m/W_g (mS/ μm) hard to increase $\rightarrow C_{end}/g_m$ prevents f_τ scaling.

Shorter gate lengths degrade electrostatics \rightarrow reduced $g_m/G_{ds} \rightarrow$ reduced f_{max}, f_τ

Towards faster HEMTs: MOS-HEMTs

Scaling limit: gate insulator thickness

HEMT: InAlAs barrier: tunneling, thermionic leakage
 solution: replace InAlAs with high-K dielectric
 2nm ZrO₂ ($\epsilon_r=25$): adequately low leakage

Scaling limit: source access resistance

HEMT: InAlAs barrier is under N+ source/drain
 solution: regrowth, place N+ layer on InAs channel

Target ~10nm node

~0.3nm EOT, 3nm thick channel
 1.2 to 1.5 THz f_τ .

Jun Wu, UCSB, IEEE EDL, 2018

ICs

mm-Wave IC design: the challenges

Transistor gains are low: f_{signal} is significant fraction of f_{max} .
match for optimum gain, noise, or power.

Device dimensions are a significant fraction of a wavelength
Even short lengths of wiring add serious parasitics

Transmission-line losses are high

low Q in VCO resonators and filters

high combining losses in PAs: low power, low efficiency

several dB added noise in LNAs.

Thin-film microstrip: inverted or right-side-up

Packages

The mm-wave module design problem

How to make the IC electronics fit ?

100+ GHz arrays: $\lambda_0/2$ element spacing is very small.

Antennas on or above IC \rightarrow IC channel spacing = antenna spacing

\rightarrow **limited IC area to place circuits**

How to avoid catastrophic signal distribution losses ?

long-range, high-gain arrays: array size can be large.

ICs beside array \rightarrow very long wires between beam former and antenna

\rightarrow **potential for very high signal distribution losses**

How to remove the heat ?

100+ GHz arrays: element spacing is very small.

If antenna spacing = IC channel spacing, then power density is very large

mm-wave/sub-mm-wave packaging

Not all systems steer in two planes...
...some steer in only one.

Not all systems steer over 180 degrees...
...some steer a smaller angular range

Arrays can often be linear (1D), instead of rectangular (2D)
Element spacing can often be greater than $\lambda/2$.

→ Array packaging then greatly simplified.

Concept: Tile for linear arrays

Terrestrial system: horizontal steering only → linear array.
Space at edges of linear array: room for III-V PAs, LNAs.
Alternating-sides feed: 2mm pitch → room for large GaN PAs.
Mounting directly on metal carrier → heatsinking.

140GHz array module design

Simulations good: working with Kyocera. June tapeout ?

140GHz Indoor Gigabit Network Demonstration

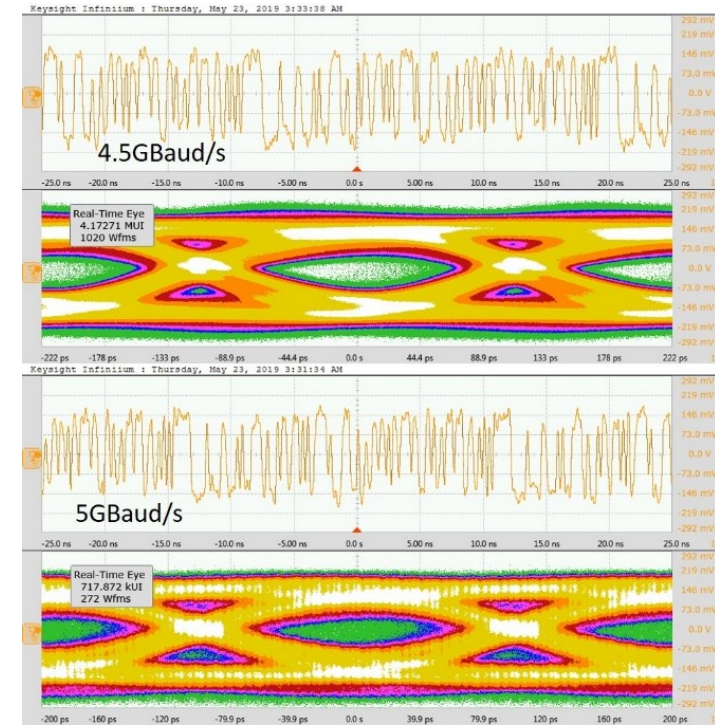

a)

b)

c)

Concept: module for small angular scanning

Terrestrial system: horizontal + vertical steering \rightarrow rectangular array.

Limited angular steering range (installation) \rightarrow spacing $\gg \lambda/2$

Endfire / edge-card geometry: room for III-V PAs, LNAs.

Mounting directly on metal carrier \rightarrow heatsinking.

If Vivaldi's are replaced with dipoles, element spacing can be reduced to $\lambda/2$.

\rightarrow potential for wider angular scanning

$\lambda/2$ -spaced 2-D Arrays

Tray design

Vertical spacings become very small
difficult to remove heat

Split-block / waveguide design

heatsinking maintained
difficult to manufacture

Wireless above 100GHz

Wireless above 100 GHz

Massive capacities

large available bandwidths

massive spatial multiplexing in base stations and point-point links

Very short range: few 100 meters

short wavelength, high atmospheric losses. Easily-blocked beams.

IC Technology

All-silicon for short ranges below 250 GHz.

III-V LNAs and PAs for longer-range links. Just like cell phones today

III-V frequency extenders for 340GHz and beyond

The challenges

spatial multiplexing: computational complexity

packaging: fitting signal channels in very small areas

In case of questions

140 GHz spatially multiplexed base station

75 GHz spatially multiplexed base station

Boldface indicates parameters to enter, other parameters are calculated by formula and should be left alone

If we use instead a 75GHz carrier, the range increases to 325 meters (vs. 250 meters) but the handset becomes 16mm×16mm (vs. 9mm×9mm), and the hub array becomes 9mm×655mm (vs. 5mm×350mm)

Or, use a 4×4 (8mm×8mm) handset array, and the range becomes 210 meters.
